1 Crypto

1.1 Overview

We knew about 2 types of ciphers: substitution and transposition. Substitution - ciphers where units of plain text are changed by some rule to other. In transposition ciphers units stay unchanged, but change their place in plaintext

1.2 Affine

Affine - monoalphabetic substitution cipher, where each letter changed to character by function

$$E(x) = (ax + b) \bmod m \quad (1)$$

, where a and b are keys, x is numerical form of letter, counted from beginin of alphabet (A=0, b=1 ...) and m is numbers of symbols in that alphabet. Also a and m should be coprime, because if they are not, decryption might be impossible. Affine cipher has all weaknesses of monoalphabetic substitutional ciphers. There are only 12 numbers that are coprime with 26 and less then 26. Also only 26 values for b. $12 \cdot 26 = 312$ posible a,b combinations. Becouse of this, it can be easily carcked with bruteforce. Also it is weak for frequently analyze, and if cryptanalyst can discover plaintext of 2 cipher characters, he can obtain key by solving simultaneous equation. For decryption we use function

$$D(x) = a^{-1}(x - b) \bmod m \quad (2)$$

.

1.2.1 Encrypting example

1. Let plaint text be

'All world is stage'

and a=9 b=3

2. Turn all symbols to numbers beginning from A (A=0, B=1 ...)
plain text will be

0 11 11 22 14 17 11 3 8 18 18 19 0 6 4

3. Symbol by symbol we process that numbers through

$$E(x) = (ax + b) \bmod m \quad (3)$$

For example. $(9 \cdot 0 + 3) \bmod 26 = 3$. Result

3 24 24 19 25 0 24 4 23 9 9 18 3 5 13

4. At the end we need to put symbols instead of numbers, inversing first step. Our ciphertext is - DYY TZAYE XJ JSDFN

1.2.2 Decrypting example

1. Let ciphertext be

DYY TZAYE XJ JSDFN

. We also know key - a=9 b=3

2. Turn all symbols to numbers beginning from A (A=0, B=1 ...)
plain text will be

3 24 24 19 25 0 24 4 23 9 9 18 3 5 13

3. Next we need to compute

$$a^{-1} \quad (4)$$

There're various methods to do that. At least we got that equal 3.

4. We produce computation by decryption formula for each number. For example

$$3 * (3 - 9) \bmod 26 = 0 \quad (5)$$

and get result

0 11 11 22 14 17 11 3 8 18 18 19 0 6 4

5. At the end we need to put symbols instead of numbers, inversing first step. Our plain text is - ALL WORLD IS STAGE

1.3 Playfair

Playfair - symmetric and first literal digram substitution cipher, invented by Charles Wheatstone, but named by Lord Playfair who promoted use of that cipher. Harder to break, than single letter substitutional ciphers, cause it's harder to make frequency analysis for bigrams. Nowadays it is not used cause even smartphones easily break it in seconds.

1.3.1 Encryption

To encrypt we use 5x5 square starting from keyword and finished by rest of ordered alphabet without J (suppose J==I) like:

```
S O M E K
Y A B C D
F G H I L
N P Q R T
U V W X Z
```

Also we divide our plaintext in bigrams like:

IN TE LX LI GE NC EX

If there're repeated letters or last one hasn't got pair, we add X after letter. Then we use 4 rules to crypt that message with Playfair cipher.

1. If 2 symbols of bigram stays on one row, we substitute them with right neighbors each.
2. .. stays on one col, substitute with below letters.

3. .. stays on vertexes of rectangle, change them on letters, that stays on their row and also are vertexes of that rectangle
4. If there is no below or right side neighbor, we took first from opposite side (first row, or first col).

Let's crypt our message

1. IN stays on vertexes of F, I, X, U rectangle and we change them to FR
2. TE change to RK
3. LX = IZ
4. LI is on one row, we change them to right neighbor, i-¿L, but L is last in row, we change it to first letter: L-¿F
5. GE = IO
6. NC = RY
7. EX = CE

Decrypting goes same, but uses inversed rules.

1.4 ADFGVX

ADFGVX (ADFGX in origin) is cipher that was originally invented by Lt. Fritz Nebel and upgraded in 1918. It uses both substitutional and transpositional methods, that made it very strong for usage in WWI. Cipher is named after six characters that used in it. Those was chosen because they look very different in Morse code, that makes errors more rare.

Encryption Let's encrypt 'RFC'. First we need 5x5 square filled with secret mixed alphabet - substitution key

```

A D F G X
A Z X D A W
D V R T U S
F L M O Q E
G Y I P F G
X H K N B C

```

I and J encrypted like one to make 26 six alphabet fit in 25 cells.

Using that for each letter in plaintext we take row letter and column letter.
R = DD F = GG C = XX DDGGXX

Second step is transposition. We write our ciphertext under transposition key.

```

H A L F
D D G G
X X

```

Then we sort letter in HALF in alphabetical order, changing cols in table,

```

A F H L
D G D G
X X

```

and write by columns from up to below. We got ciphertext = DX GD XG

Decryption is just inverse of each step using both keys.

1.4.1 Encrypting text with Vigenere

My plain text was

memories can be vile, repulsive little brutes. like children, i suppose.
haha. but can we live without them? although, why not? we aren't
contractually tied down to rationality! there is no sanity clause! so when
you find yourself locked onto an unpleasant train of thought, heading for
the places in your past where the screaming is unbearable, remember
there's always madness. you can just step outside, and close the door
on all those dreadful things that happened. you can lock them away.
forever. madness is the emergency exit.

Firstly I took out all punctuation and spaces

memoriescanbevilerepulsivelittlebruteslikechildrenisupposehahabut
canwelivewithoutthemalthoughwhynotwearentcontractuallytieddowntor
ationalitythereisnosanityclausesowhenyoufindyourselflockedontoanu
npleasanttrainofthoughttheadngfortheplacesinyourpastwherethescrea
mingisunbearableremembertheresalwaysmadnessyoucanjuststepoutsidea
ndclosethedooronallthosedreadfulthingsstathappenedyoucanlockthema
wayforevermadnessistheemergencyexit

Key=JOKER, after multiplying to length of ciphertext mod length of key, i have

JOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJO
KERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKE
RJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJ
OKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOK
ERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKER
JOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJOKERJO
KERJOKERJOKERJOKERJOKER

Using Vigenere's square I took column marked as encrypting letter, and row marked with letter that stays whos position is same as encrypting letter.
